## Pearson's chi-squared test in one shot

$$\chi^2 = \sum \frac{(\text{Observed} - \text{Expected})^2}{\text{Expected}} \sim \text{Chi Square of } df$$

$df$  = numer of classes – number of estimated parameters – 1

All expected  $\geq 5$

## Chapter 10. Goodness-of-fit Tests

**Def.** Suppose one does an experiment of extracting  $n$  balls of  $t$  different colors from a jar, replacing the extracted ball after each draw. Balls from the same color are equivalent. Denote the variable which is the number of extracted balls of color  $i$  ( $i = 1, \dots, t$ ) as  $X_i$ , and denote as  $p_i$  the probability that a given extraction will be in color  $i$ . The probability distribution function of the vector  $(X_1, \dots, X_t)$  is called the **multinomial distribution**, which is equal to

$$\begin{aligned} p_{X_1, \dots, X_t}(k_1, \dots, k_t) &= \mathbb{P}(X_1 = k_1, \dots, X_t = k_t) \\ &= \binom{n}{k_1, \dots, k_t} p_1^{k_1} \dots p_t^{k_t} \end{aligned}$$

where  $k_i \in \{0, 1, \dots, n\}$ ,  $1 \leq i \leq t$ ,  $\sum_{i=1}^t k_i = n$ , and  $p_1 + \dots + p_t = 1$ .

**Thm** Suppose  $(X_1, \dots, X_t)$  follows the multinomial distribution with parameters  $n$  and  $(p_1, \dots, p_t)$  with  $p_i \geq 0$  and  $\sum_i p_i = 1$ . Then

1.  $X_i \sim \text{Binomial}(n, p_i)$  and hence

$$\mathbb{E}[X_i] = np_i$$

$$\text{Var}(X_i) = np_i(1 - p_i)$$

2.  $\text{Cov}(X_i, X_j) = -np_i p_j, i \neq j.$  (negative correlated)

3.  $M_{X_1, \dots, X_t}(s_1, \dots, s_t) = (p_1 e^{s_1} + \dots + p_t e^{s_t})^n.$

Proof

(3)

$$\begin{aligned}
 M_{X_1, \dots, X_t}(\mathbf{s}_1, \dots, \mathbf{s}_t) &= \mathbb{E} \left[ e^{X_1 \mathbf{s}_1 + \dots + X_t \mathbf{s}_t} \right] \\
 &= \sum_{\substack{k_1, \dots, k_t=0 \\ k_1 + \dots + k_t = n}}^n \binom{n}{k_1, \dots, k_t} p_1^{k_1} \dots p_t^{k_t} e^{k_1 \mathbf{s}_1 + \dots + k_t \mathbf{s}_t} \\
 &= \sum_{\substack{k_1, \dots, k_t=0 \\ k_1 + \dots + k_t = n}}^n \binom{n}{k_1, \dots, k_t} (p_1 e^{\mathbf{s}_1})^{k_1} \dots (p_t e^{\mathbf{s}_t})^{k_t} \\
 &= (p_1 e^{\mathbf{s}_1} + \dots + p_t e^{\mathbf{s}_t})^n
 \end{aligned}$$

(1) To find  $M_{X_i}(\mathbf{s}_i)$ , we simply set  $\mathbf{s}_j \equiv 0$  for  $j \neq i$ . Hence

$$M_{X_i}(\mathbf{s}_i) = \left( \underbrace{p_1 + \dots + p_{i-1} + p_{i+1} + \dots + p_t}_{=1-p_i} + p_i e^{\mathbf{s}_i} \right)^n \implies X_i \sim \text{Binomial}(n, p_i)$$

(2) Set  $M := M_{X_1, \dots, X_t}(s_1, \dots, s_t)$ . Then for  $i \neq j$ ,

$$\frac{\partial M}{\partial s_i} = n(p_1 e^{s_1} + \dots + p_t e^{s_t})^{n-1} p_i e^{s_i}$$

$$\frac{\partial^2 M}{\partial s_i \partial s_j} = n(n-1)(p_1 e^{s_1} + \dots + p_t e^{s_t})^{n-2} p_i e^{s_i} p_j e^{s_j}$$

$\Downarrow$

$$\mathbb{E}[X_i X_j] = \left. \frac{\partial^2 M}{\partial s_i \partial s_j} \right|_{s_1 = \dots = s_t = 0} = n(n-1)(p_1 + \dots + p_t)^{n-2} p_i p_j = n(n-1)p_i p_j$$

$\Downarrow$

$$\begin{aligned} \text{Cov}(X_i, X_j) &= \mathbb{E}[X_i X_j] - \mathbb{E}[X_i] \mathbb{E}[X_j] \\ &= n(n-1)p_i p_j - np_i \times np_j \\ &= -np_i p_j \end{aligned}$$

□

From a continuous pdf to a multinomial distribution:

E.g. Let  $Y_i$  be a random sample of size  $n$  from  $f_Y(y) = 6y(1 - y)$ ,  $y \in [0, 1]$ .  
Define

$$X_i = \begin{cases} 1 & Y_i \in [0, 0.25) \\ 2 & Y_i \in [0.25, 0.5) \\ 3 & Y_i \in [0.5, 0.75) \\ 4 & Y_i \in [0.75, 1) \end{cases}$$

Find the distribution of  $(X_1, \dots, X_n)$ .

Sol.  $(X_1, X_2, X_3, X_4)$  follows multinomial distribution with parameters  $(p_1, p_2, p_3, p_4)$  where

$$p_1 = \int_0^{\frac{1}{4}} 6y(1 - y)dy = \dots = \frac{5}{32},$$

and by symmetry,

$$p_4 = p_1 = \frac{5}{32} \quad \text{and} \quad p_2 = p_3 = \frac{1}{2} (1 - p_1 - p_4) = \frac{11}{32}.$$

□

**Remark** In this way, we transform the outcomes, any values between  $[0, 1]$ , into **categorical data**. This chapter is about

## Analysis of Categorical Data

## Chapter 10. Goodness-of-fit Tests

## Rationale

! We want to test if the c.d.f.  $F_Y(\cdot)$  is given by the true c.d.f.  $F_0(\cdot)$ , i.e.,

$$H_0 : F_Y(y) = F_0(y) \quad \text{v.s.} \quad H_1 : F_Y(y) \neq F_0(y)$$

~ By properly partitioning the domain, the random sample should follow  
*an induced multinomial distribution.*

$\Rightarrow$  Then testing  $F_Y(\cdot) = F_0(\cdot)$  reduces to testing the induced multinomial distribution of the following form:

$$H_0 : p_1 = p'_1, \dots, p_n = p'_n$$

v.s.

$$H_1 : p_i \neq p'_i \quad \text{for at least one } i$$

## How

1. Suppose we are sampling from the c.d.f.  $F(y)$
2. Divide the range of the distribution into  $k$  mutually exclusive and exhaustive intervals, say  $I_1, \dots, I_k$ .
3. Let  $\pi_i = \mathbb{P}(X \in I_i)$ ,  $i = 1, \dots, k$ .
4. Let  $O_1, \dots, O_k$  be the respective observed numbers of the observations  $X_1, \dots, X_n$  in the intervals  $I_1, \dots, I_k$ .
5. Then  $O = (O_1, \dots, O_k) \sim$  multinomial distribution with  $(\pi_1, \dots, \pi_k)$ , i.e.,

$$\mathbb{P}(O_1 = o_1, \dots, O_k = o_k) = \frac{n!}{\prod_{i=1}^k o_i!} \prod_{i=1}^k \pi_i^{o_i}$$

with  $\sum_{i=1}^k \pi_i = 1$ ,  $\sum_{i=1}^k o_i = n$ , and

$$\mathbb{E}[O_i] = n\pi_i =: e_i, \quad \text{Var}(O_i) = n\pi_i(1 - \pi_i)$$

6. When  $k = 2$ , by CLT, as  $n \rightarrow \infty$ ,

$$\begin{aligned}
 \frac{O_1 - n\pi_1}{\sqrt{n\pi_1(1 - \pi_1)}} &\xrightarrow{d} N(0, 1) \quad \implies \quad \frac{(O_1 - n\pi_1)^2}{n\pi_1(1 - \pi_1)} \xrightarrow{d} \chi_1^2 \\
 &\parallel \\
 &\frac{(O_1 - n\pi_1)^2}{n\pi_1} + \frac{(O_2 - n\pi_2)^2}{n\pi_2} \\
 &\parallel \\
 &\frac{(O_1 - e_1)^2}{e_1} + \frac{(O_2 - e_2)^2}{e_2}
 \end{aligned}$$

Hence, as  $n \rightarrow \infty$ ,

$$\sum_{i=1}^k \frac{(O_i - e_i)^2}{e_i} \xrightarrow{d} \chi_{k-1}^2$$

7. For general  $k$ ,

$$\sum_{i=1}^k \frac{(O_i - n\pi_i)^2}{n\pi_i} = \sum_{i=1}^k \frac{(O_i - e_i)^2}{e_i}$$

follows a complicated, but exact, distribution, from which, one can show

$$\sum_{i=1}^k \frac{(O_i - e_i)^2}{e_i} \xrightarrow{d} \chi_{k-1}^2$$

$\Downarrow$

**Thm.** When  $n$  is large enough, namely, when  $n\pi_i \geq 5$  for all  $i$ ,

$$D = \sum_{i=1}^k \frac{(O_i - e_i)^2}{e_i} \underset{\sim}{\overset{appr.}{\chi_{k-1}^2}}.$$

**Rmk:** The above is called Pearson's chi-square test. It is asymptotically equivalent to the generalized likelihood ratio test.

## Alternative: G-test

– the likelihood ratio test for multinomial model

1. Under  $H_0 : \pi_i = p_i, i = 1, \dots, k$ , the MLE of  $\pi_i$  are

$$\tilde{\pi}_i = p_i = \frac{np_i}{n} = \frac{e_i}{n}, \quad \forall i.$$

2. When there are no constraints, for  $i = 1, \dots, k-1$ ,

$$\frac{\partial}{\partial \pi_i} \ln L(\pi_1, \dots, \pi_{k-1} | o_1, \dots, o_k) = 0, \quad 1 \leq i \leq k-1$$

$$\Updownarrow$$

$$\frac{o_i}{\hat{\pi}_i} = \frac{o_k}{1 - \hat{\pi}_1 - \dots - \hat{\pi}_{k-1}}, \quad 1 \leq i \leq k-1$$

$$\Updownarrow$$

$$\hat{\pi}_i = \frac{o_i}{n}, \quad 1 \leq i \leq k.$$

$\Rightarrow$

$$\begin{aligned}\lambda &:= \ln \left( \frac{L(\widetilde{\pi}_1, \dots, \widetilde{\pi}_{k-1} | \mathbf{o}_1, \dots, \mathbf{o}_k)}{L(\widehat{\pi}_1, \dots, \widehat{\pi}_{k-1} | \mathbf{o}_1, \dots, \mathbf{o}_k)} \right) = \log \left( \frac{\prod_{i=1}^k \widetilde{\pi}_i^{o_i}}{\prod_{i=1}^k \widehat{\pi}_i^{o_i}} \right) \\ &= \sum_{i=1}^k o_i \ln \left( \frac{\widetilde{\pi}_i}{\widehat{\pi}_i} \right) \\ &= \sum_{i=1}^k o_i \ln \left( \frac{e_i}{o_i} \right)\end{aligned}$$

Critical region:  $\lambda < \lambda_* < 0$ .

Def.

$$G := -2\lambda = -2 \sum_{i=1}^k o_i \ln \left( \frac{e_i}{o_i} \right) = 2 \sum_{i=1}^k o_i \ln \left( \frac{o_i}{e_i} \right)$$

$G \overset{\text{approx.}}{\sim} \chi_{k-1}^2$  for large  $n$ .

Critical region:  $G \geq G_* = \chi_{1-\alpha, k-1}^2$ .

## Relation G-test and Pearson's Chi square test

By second order Taylor expansion around 1,

$$\begin{aligned} G &= -2 \sum_{i=1}^k o_i \ln \left( \frac{e_i}{o_i} \right) \\ &\approx -2 \sum_{i=1}^k o_i \left[ \left( \frac{e_i}{o_i} - 1 \right) - \frac{1}{2} \left( \frac{e_i}{o_i} - 1 \right)^2 \right] \\ &= -2 \sum_{i=1}^k (e_i - o_i) + \sum_{i=1}^k o_i \left( \left( 1 - \frac{o_i}{e_i} \right) + \frac{o_i}{e_i} \right) \left( \frac{e_i}{o_i} - 1 \right)^2 \\ &= 0 + \sum_{i=1}^n \frac{o_i^2}{e_i} \left( 1 - \frac{o_i}{e_i} \right)^3 + \sum_{i=1}^k \frac{(e_i - o_i)^2}{e_i} \\ &\approx \sum_{i=1}^k \frac{(e_i - o_i)^2}{e_i} \\ &\quad \parallel \\ &\quad D \end{aligned}$$

$\therefore$  Pearson's Chi-square test is an approximation of G-test.

E.g. 1 *Benford's law*:

<b>Table 10.3.1</b>	
Digit, $i$	$\log_{10}(i + 1) - \log_{10}(i)$
1	0.301
2	0.176
3	0.125
4	0.097
5	0.079
6	0.067
7	0.058
8	0.051
9	0.046

Initial digits

Digit	Observed, $k_i$
1	111
2	60
3	46
4	29
5	26
6	22
7	21
8	20
9	20
	<hr/> 355

Use this law to check whether the bookkeepers have made up entries.

Assume that bookkeepers are not aware of Benford's law.

Sol. The test should be

$$H_0 : p_1 = p_{10}, \dots, p_9 = p_{90}$$

v.s.

$$H_1 : p_i \neq p_{i0} \quad \text{for at least one } i = 1, \dots, 9.$$

Critical region:  $(\chi^2_{.95,8}, \infty) = (15.507, \infty)$ .

Compute the  $D$  and  $G$  scores:

Digit	$o_i$	$p_i$	$e_i$	$(o_i - e_i)^2 / e_i$	$2o_i \ln(e_i / o_i)$
1	111	0.301

$P$ -value = 0.601  $\implies$  No.

## Chapter 10. Goodness-of-fit Tests

$p_i$ are known	$p_i$ are unknown
$D = \sum_{i=1}^t \frac{(X_i - np_i)^2}{np_i}$	$D_1 = \sum_{i=1}^t \frac{(X_i - n\hat{p}_i)^2}{n\hat{p}_i}$
$\chi^2$ with f.d. $t - 1$	$\chi^2$ with f.d. $t - 1 - s$
$d = \sum_{i=1}^t \frac{(k_i - np_{i0})^2}{np_{i0}}$	$d_1 = \sum_{i=1}^t \frac{(k_i - n\hat{p}_{i0})^2}{n\hat{p}_{i0}}$
$np_{i0} \geq 5$	$n\hat{p}_{i0} \geq 5$
$d > \chi^2_{1-\alpha, t-1}$	$d_1 > \chi^2_{1-\alpha, t-1-s}$

†  $s$  is the number of unknown parameters.

df = number of classes - 1 - number of unknown parameters.

E.g. 1 Binomial data: 4096 students, each shots basketball 4 times. Let  $X_i$  be the number of hits for the  $i$ th student.

Number of Hits, $i$	Obs. Freq., $k_i$
0	1280
1	1717
2	915
3	167
4	17

People believe that  $X_i$  should following binomial(4,  $p$ ), that is, shotting basketball should be something like trying to get red chocolate beans from a jar of beans of two colors.

Find the MLE for  $p$ . Use the data to make a conclusion.

Sol. 1)  $H_0 : X_i \sim \text{binomial}(4, p)$ .

2) Under  $H_0$ , the MLE for  $p$  is  $p_e = \dots = 0.251$

3) Compute the expected frequencies:

<b>Table 10.4.1</b>		
Number of Hits, $i$	Obs. Freq., $k_i$	Estimated Exp. Freq., $n \hat{p}_{i_0}$
$r'_i s \left\{ \begin{array}{l} 0 \\ 1 \\ 2 \\ 3 \\ 4 \end{array} \right.$	$\begin{array}{c} 1280 \\ 1717 \\ 915 \\ 167 \\ 17 \end{array}$	$\begin{array}{c} 1289.1 \\ 1728.0 \\ 868.6 \\ 194.0 \\ 16.3 \end{array}$

$$\implies \quad \mathcal{d}_1 = \dots = 6.401.$$

4) Critical region:  $(\chi_{.95, 5-1-1}^2, +\infty) = (7.815, +\infty)$

5) Conclusion: Fail to reject.

6) Alternatively,  $P$ -value  $= \mathbb{P}(\chi_3^2 \geq 6.401) = 0.094$ , ... discuss...

□

E.g. 2 Does the number of death per day follow the Poisson distribution?

Number of Deaths, $i$	Obs. Freq., $k_i$
0	162
1	267
2	271
3	185
4	111
5	61
6	27
7	8
8	3
9	1
10+	0
	<hr/> 1096

Sol. 1) Let  $X_i$  be the number of death in  $i$ th day,  $1 \leq i \leq 1096$ .

2)  $H_0 : X_i$  follow  $\text{Poisson}(\lambda)$ .

3) The MLE for  $\lambda$  is:  $\lambda_e = \dots = 2.157$ .

4) Compute the expected frequencies:

<b>Table 10.4.2</b>		
Number of Deaths, $i$	Obs. Freq., $k_i$	Est. Exp. Freq., $n \hat{p}_{i_0}$
0	162	126.8
1	267	273.5
2	271	294.9
3	185	212.1
4	111	114.3
5	61	49.3
6	27	17.8
7	8	5.5
8	3	1.4
9	1	0.3
10+	0	0.1
	1096	1096

<b>Table 10.4.3</b>		
Number of Deaths, $i$	Obs. Freq., $k_i$	Est. Exp. Freq., $n \hat{p}_{i_0}$
$r_1, r_2, \dots, r_8$	0	126.8
	1	273.5
	2	294.9
	3	212.1
	4	114.3
	5	49.3
	6	17.8
	7+	7.3
	1096	1096

$$\implies d_1 = \dots = 25.98.$$

5)  $P\text{-value} = \mathbb{P}(\chi_{1,8-1-1}^2 \geq 25.98) = 0.00022$ . Reject!

□

## Chapter 10. Goodness-of-fit Tests

E.g. 1 Whether are the two ratings independent?

<b>Table 10.5.5</b>					
		Ebert Ratings			Total
		Down	Sideways	Up	
Siskel Ratings	Down	24	8	13	45
	Sideways	8	13	11	32
	Up	10	9	64	83
	Total	<u>42</u>	<u>30</u>	<u>88</u>	<u>160</u>

E.g. 2 Whether is the suicide rate independent of the mobility factor?

**Table 10.5.7**

City	Suicides per 100,000, $x_i$	Mobility Index, $y_i$	City	Suicides per 100,000, $x_i$	Mobility Index, $y_i$
New York	19.3	54.3	Washington	22.5	37.1
Chicago	17.0	51.5	Minneapolis	23.8	56.3
Philadelphia	17.5	64.6	New Orleans	17.2	82.9
Detroit	16.5	42.5	Cincinnati	23.9	62.2
Los Angeles	23.8	20.3	Newark	21.4	51.9
Cleveland	20.1	52.2	Kansas City	24.5	49.4
St. Louis	24.8	62.4	Seattle	31.7	30.7
Baltimore	18.0	72.0	Indianapolis	21.0	66.1
Boston	14.8	59.4	Rochester	17.2	68.0
Pittsburgh	14.9	70.0	Jersey City	10.1	56.5
San Francisco	40.0	43.8	Louisville	16.6	78.7
Milwaukee	19.3	66.2	Portland	29.3	33.2
Buffalo	13.8	67.6			

$$\bar{x} = 20.8 \quad \text{and} \quad \bar{y} = 56.0$$

**Table 10.5.8**

		Mobility Index	
		Low (<56.0)	High ( $\geq 56.0$ )
Suicide	High ( $\geq 20.8$ )	7	4
Rate	Low (<20.8)	3	11

**Thm 10.4.1** Suppose that  $n$  observations are taken on a sample space partitioned by the events  $A_1, \dots, A_r$  and  $B_1, \dots, B_c$ .

Let  $p_i = \mathbb{P}(A_i)$ ,  $q_j = \mathbb{P}(B_j)$ ,  $p_{ij} = \mathbb{P}(A_i \cap B_j)$ .

Let  $X_{ij}$  be the number of observations belonging to  $A_i \cap B_j$ .

a) Provided that  $np_{ij} \geq 5$  for all  $i, j$ , the r.v.

$$D_2 = \sum_{i=1}^r \sum_{j=1}^c \frac{(X_{ij} - np_{ij})^2}{np_{ij}} \sim \text{Chi square of f.d. } rc - 1$$

b) To test  $H_0 : A_i$ 's are independent of  $B_j$ 's, calculate the test statistic

$$d_2 = \sum_{i=1}^r \sum_{j=1}^c \frac{(k_{ij} - n\hat{p}_i\hat{q}_j)^2}{n\hat{p}_i\hat{q}_j}$$

where  $\hat{p}_i$  and  $\hat{q}_j$  are MLE's for  $p_i$  and  $q_j$ , respectively.

Provided that  $n\hat{p}_i\hat{q}_j \geq 5$  for all  $i, j$ , the critical region is

$$(\chi_{1-\alpha, (r-1)(c-1)}^2, +\infty)$$

E.g. 1 Sol: Compute the expected frequencies:

Table 10.5.6					
		Ebert Ratings			Total
		Down	Sideways	Up	
Siskel Ratings	Down	24 (11.8)	8 (8.4)	13 (24.8)	45
	Sideways	8 (8.4)	13 (6.0)	11 (17.6)	32
	Up	10 (21.8)	9 (15.6)	64 (45.6)	83
	Total	42	30	88	160

$$\implies d_2 = \dots = 45.37$$

Critical region is

$$(\chi_{0.99, (3-1) \times (3-1)}^2, +\infty) = (13.277, +\infty)$$

Alternatively  $P\text{-value} = \mathbb{P}(\chi_4^2 \geq 45.37) = 3.33 \times 10^{-9}$ .

Rejection at  $\alpha = 0.01$ .

□

E.g. 2 Sol: Compute the expected frequencies:

<b>Table 10.5.9</b>			
		Mobility Index	
		Low (<56.0)	High (≥56.0)
Suicide Rate	High (≥20.8)	4.4*	6.6
	Low (<20.8)	5.6	8.4
* $\hat{E}(X_{11}) = 4.4$ does not quite satisfy the " $n\hat{p}_i\hat{q}_j \geq 5$ " restriction stated in Theorem 10.5.1, but 4.4 is close enough to 5 to maintain the integrity of the $\chi^2$ approximation.			

$$\implies d_2 = \dots = 4.57$$

Critical region is

$$(\chi_{0.95, (2-1) \times (2-1)}^2, +\infty) = (3.41, +\infty)$$

Alternatively  $P\text{-value} = \mathbb{P}(\chi_1^2 \geq 4.57) = 0.033$

Rejection at  $\alpha = 0.05$ .
